Introduction: Natural language processing

The processing of natural language is important for many applications, including the following:

- ▶ Translation
- ▶ Sentiment analysis
- ▶ Web search
- ▶ Language modeling

Natural language processing (NLP) can analyze language

- ▶ **syntactically**: Parse grammar, check spelling etc.
- ▶ **semantically**: Understand meaning, find synonyms etc.

Vector space model

In this model of information retrieval for NLP, documents are represented by a vector of the counts of terms occurring in them. Terms can be words, keywords or phrases. Vector operations can now be used to compare documents for similarity:

$$\cos \theta = \frac{v_1 \cdot v_2}{\|v_1\| \|v_2\|}$$

Vector Representation of word

one-hot representation:

The dimension of each word would be the number of unique words in the corpus.

Book = [0 0 0 1 0 0 0 0 0 0 0 0 0 0 0]

Co-occurrence Matrix:

Silence is the language of God, all else is poor translation.

(Rumi 1207 , 1273)

	Silence	is	language	God
Silence	0	1	0	0
is	1	0	0	0
language	0	1	0	0
God	0	0	1	0

Word2vec

Word2vec is a language model that learns about the relationship between words. The output vectors show interesting relationships, e. g:

$$\text{vec}(\text{"king"}) - \text{vec}(\text{"man"}) + \text{vec}(\text{"woman"}) \approx \text{vec}(\text{"queen"}).$$

The model should put words that occur in similar context into clusters:

Word2vec

$$\begin{aligned} \text{dist}(\text{vec}(\text{"king"}), \text{vec}(\text{"man"})) &\approx \\ \text{dist}(\text{vec}(\text{"queen"}), \text{vec}(\text{"woman"})) \end{aligned}$$

$$\Rightarrow \text{vec}(\text{"king"}) - \text{vec}(\text{"man"}) \approx \text{vec}(\text{"queen"}) - \text{vec}(\text{"woman"})$$

$$\Rightarrow \text{vec}(\text{"king"}) - \text{vec}(\text{"man"}) + \text{vec}(\text{"woman"}) \approx \text{vec}(\text{"queen"}).$$

Word2vec

Methods :

- ▶ CBOW (Continuous Bag of words)
- ▶ Skip-Gram

The CBOW architecture predicts the current word based on the context.

The skip-Gram predicts surrounding words given the current words.

The skip-gram model

Source Text

Training Samples

<div>The quick brown fox jumps over the lazy dog.</div>	→	(the, quick) (the, brown)
<div>The quick brown fox jumps over the lazy dog.</div>	→	(quick, the) (quick, brown) (quick, fox)
<div>The quick brown fox jumps over the lazy dog.</div>	→	(brown, the) (brown, quick) (brown, fox) (brown, jumps)
<div>The quick brown fox jumps over the lazy dog.</div>	→	(fox, quick) (fox, brown) (fox, jumps) (fox, over)

The skip-gram model

The continuous-bag-of-words model

- ▶ The skip-gram model tries to guess context words based on the current word, the CBOW model goes the other way
- ▶ The one-hot vectors of the surrounding words are summed up (counting the context words), the order of the words is not considered, this is the network input
- ▶ The current word's one-hot vector is the desired output

Next steps

- ▶ Choose a minimal, but interesting corpus of English words
- ▶ Select a source of text to train the network from
 - ▶ Browse through Wikipedia or similar websites
 - ▶ Extract long enough passages only consisting of our limited vocabulary
- ▶ Generate skip-gram or CBOW pairs for network training
- ▶ Desired size of word vector / hidden layer size
- ▶ Potential problems with network training (large number of weights)
- ▶ Use test data to check prediction accuracy, adjust training parameters if necessary
